

nasm x86 Assembly Quick Reference ("Cheat Sheet")

Instructions			Stack Frame																										
Mnemonic	Purpose	Examples	(example without ebp or local variables)																										
mov <i>dest,src</i>	Move data between registers, load immediate data into registers, move data between registers and memory.	mov eax,4 ; Load constant into eax mov ebx,eax ; Copy eax into ebx mov ebx,[123] ; Copy ebx to memory address 123	<table><tr><th>Contents</th><th>off esp</th></tr><tr><td>caller's variables</td><td>[esp+12]</td></tr><tr><td>Argument 2</td><td>[esp+8]</td></tr><tr><td>Argument 1</td><td>[esp+4]</td></tr><tr><td>Caller Return Address</td><td>[esp]</td></tr></table>			Contents	off esp	caller's variables	[esp+12]	Argument 2	[esp+8]	Argument 1	[esp+4]	Caller Return Address	[esp]														
Contents	off esp																												
caller's variables	[esp+12]																												
Argument 2	[esp+8]																												
Argument 1	[esp+4]																												
Caller Return Address	[esp]																												
push <i>src</i>	Insert a value onto the stack. Useful for passing arguments, saving registers, etc.	push ebp	my_sub: # Returns first argument mov eax,[esp+4] ret																										
pop <i>dest</i>	Remove topmost value from the stack. Equivalent to "mov <i>dest</i> ,[esp] add esp,4"	pop ebp	(example when using ebp and two local variables)																										
call <i>func</i>	Push the address of the next instruction and start executing func.	call print_int	<table><tr><th>Contents</th><th>off ebp</th><th>off esp</th></tr><tr><td>caller's variables</td><td>[ebp+16]</td><td>[esp+24]</td></tr><tr><td>Argument 2</td><td>[ebp+12]</td><td>[esp+20]</td></tr><tr><td>Argument 1</td><td>[ebp+8]</td><td>[esp+16]</td></tr><tr><td>Caller Return Address</td><td>[ebp+4]</td><td>[esp+12]</td></tr><tr><td>Saved ebp</td><td>[ebp]</td><td>[esp+8]</td></tr><tr><td>Local variable 1</td><td>[ebp-4]</td><td>[esp+4]</td></tr><tr><td>Local variable 2</td><td>[ebp-8]</td><td>[esp]</td></tr></table>			Contents	off ebp	off esp	caller's variables	[ebp+16]	[esp+24]	Argument 2	[ebp+12]	[esp+20]	Argument 1	[ebp+8]	[esp+16]	Caller Return Address	[ebp+4]	[esp+12]	Saved ebp	[ebp]	[esp+8]	Local variable 1	[ebp-4]	[esp+4]	Local variable 2	[ebp-8]	[esp]
Contents	off ebp	off esp																											
caller's variables	[ebp+16]	[esp+24]																											
Argument 2	[ebp+12]	[esp+20]																											
Argument 1	[ebp+8]	[esp+16]																											
Caller Return Address	[ebp+4]	[esp+12]																											
Saved ebp	[ebp]	[esp+8]																											
Local variable 1	[ebp-4]	[esp+4]																											
Local variable 2	[ebp-8]	[esp]																											
ret	Pop the return program counter, and jump there. Ends a subroutine.	ret	my_sub2: # Returns first argument push ebp # Prologue mov ebp, esp mov eax, [ebp+8] mov esp, ebp # Epilogue																										
add <i>src,dest</i>	<i>dest=dest+src</i>	add eax,ebx # Add ebx to eax																											
mul <i>src</i>	Multiply eax and <i>src</i> as unsigned integers, and put the result in eax. High 32 bits of product go into eax.	mul ebx #Multiply eax by ebx																											
jmp <i>label</i>	Goto the instruction <i>label</i> .. Skips anything else in the way.	jmp post_mem ...																											

		post_mem:	pop ebp ret
cmp <i>a,b</i>	Compare two values. Sets flags that are used by the conditional jumps (below).	cmp eax,10	
j1 <i>label</i>	Goto <i>label</i> if previous comparison came out as less-than. Other conditionals available are: jle (<=), je (==), jge (>=), jg (>), jne (!=), and many others.	j1 loop_start ; Jump if eax<10	
Constants, Registers, Memory <p>"12" means decimal 12; "0xF0" is hex. "some_function" is the address of the first instruction of a label. Memory access (use register as pointer): "[esp]". Same as C "*"esp". Memory access with offset (use register + offset as pointer): "[esp+4]". Same as C "*(esp+4)". Memory access with scaled index (register + another register * scale): "[eax + 4*ebx]". Same as C "*(eax+ebx*4)".</p>			Registers <p>esp is the stack pointer ebp is the stack frame pointer Return value in eax Arguments are on the stack Free for use (no save needed): eax, ebx, ecx, edx Must be saved: esi, edi, ebp, esp 8 bit: ah (high 8 bits) and al (low 8 bits) 16 bit: ax 32 bit: eax 64 bit: rax</p>

The Intel [Software Developer's Manuals](#) are incredibly long, boring, and complete--they give all the nitty-gritty details. [Volume 1](#) lists the processor registers in Section 3.4.1. [Volume 2](#) lists all the x86 instructions in Section 3.2. [Volume 3](#) gives the performance monitoring registers in Section. For Linux, the [System V ABI](#) gives the calling convention on page 39. Also see the Intel [hall of fame](#) for historical info. [Sandpile.org](#) has a good opcode table. [Ralph Brown's Interrupt List](#) is the definitive reference for all interrupt functions. See just the [BIOS interrupts](#) for interrupt-time code.
